

Problem 1. Zygmund p58 exercise 01

(a) There is an analogue for bases different from 10 of usual decimal expansion of number. If b is an integer larger than 1 and $0 < x < 1$, show that there exist integral coefficient c_k , $0 \leq c_k < b$, such that $x = \sum_{k=1}^{\infty} c_k b^{-k}$. Furthermore, show that expansion is unique unless $x = cb^{-k}$, in which case there are two expansions.

(b) When $b = 3$, the expansion is called the triadic or ternary expansion of x . Show that Cantor set consist of point in $[0, 1]$ which has triadic representation such that c_k is either 0 or 2, namely,

$$\mathcal{C} = \{x \in [0, 1] : x = \sum_{k=1}^{\infty} c_k 3^{-k}, c_k \in \{0, 2\}\}.$$

Cantor Set

^aConsider the closed interval $[0, 1]$. The first stage of the construction is to subdivide $[0, 1]$ into thirds and remove the interior of the middle third; that is, remove the open interval $(\frac{1}{3}, \frac{2}{3})$. Each successive step of the construction is essentially the same. Thus, at the second stage, we subdivide each of the remaining two intervals $[0, \frac{1}{3}]$ and $[\frac{2}{3}, 1]$ into thirds and remove the interiors, $(\frac{1}{9}, \frac{2}{9})$ and $(\frac{7}{9}, \frac{8}{9})$, of their middle thirds. We continue the construction for each of the remaining intervals. The subset of $[0, 1]$ that remains after infinitely many such operations is called the Cantor set \mathcal{C} : thus, if C_k denotes the union of the intervals left at the k th stage, then

$$\mathcal{C} = \bigcap_{k=1}^{\infty} C_k.$$

Limit Point

A point x is a limit point of the set E if every neighborhood of x contains a point $x \neq y$ such that $y \in E$.^a

In other words, x is a limit point of E if \exists a sequence $\{x_n\} \in E$, s.t. $x_n \rightarrow x$ and $x_n \neq x$.^b

Perfect Set

A closed set E is said to be a perfect set if every point of E is a limit point of E .^a

In other words, A closed set E is said to be a perfect set if $\forall x \in E, \forall \epsilon > 0, (B(x, \epsilon) \setminus \{x\}) \cap E \neq \emptyset$.

^aIbid., p. 7.

Theorem 1.7

- (i) The intersection of any number of closed sets is closed.
- (ii) The union of any number of open sets is open.

Cantor Set is perfect

To prove that Cantor Set C is a perfect set, we need to show that it is closed and every point in the set is a limit point of the set.

Since each C_k is closed, it follows from Theorem 1.7 that C is closed.

Then show that every point in C is a limit point of the set:

Case 1. Let $x \in C$ be an endpoint of $I_k \subseteq C_k$. Consider the intervals $I_k^i \subseteq C_{k+i}$ with endpoint x , let x_1 be the other endpoint of $I_k^1 \subseteq C_{k+1}$, x_2 be the other endpoint of $I_k^2 \subseteq C_{k+2}$, ..., x_n be the other endpoint of $I_k^n \subseteq C_{k+n}$.

We have

$$\begin{aligned}x_n &\rightarrow x, \\x_n &\neq x, \\x_n &\in C.\end{aligned}$$

Thus, x is a limit point of C .

Case 2. Suppose $x \in C$ is not an endpoint of any interval consisting C . $\forall n \in \mathbb{N}$, we have $x \in (a_n, b_n)$, where $a_n \in C$ and $|a_n - x| < (\frac{1}{3})^n$. Let $x_n = a_n$, $\{x_n\}$ is the sequence s.t.

$$\begin{aligned}x_n &\rightarrow x, \\x_n &\neq x, \\x_n &\in C.\end{aligned}$$

Thus, x is a limit point of C .

We can conclude that every point in C is a limit point of the set. Therefore, C is perfect.

Solution.

■

Problem 2. Zygmund p58 exercise 03

Construct a two-dimensional Cantor set in the unit square $\{(x, y) : 0 \leq x, y \leq 1\}$ as follows. Subdivide the square into nine equal parts and keep only the four closed corner squares, removing the remaining region (which forms a cross). Then repeat this process in a suitably scaled version for the remaining squares, ad infinitum. Show that the resulting set is perfect, has plane measure zero, and equals $\mathcal{C} \times \mathcal{C}$.

Solution.

Let D_0 be the unit square $\{(x, y) : 0 \leq (x, y) \leq 1\}$. Let D_k be the set remaining after i steps. Let $D = \bigcap_{k=1}^{\infty} D_k$ be the resulting set.

(a) Show that D has plane measure zero:

Since D is covered by the intervals in any D_k , we have

$$|D|_e \leq |D_k|_e = \left(\frac{4}{9}\right)^k.$$

Let $k \rightarrow \infty$, we have $|D|_e = 0$.

(b)

$$\begin{aligned} D &:= \bigcap_{k=1}^{\infty} D_k && \text{(By definition)} \\ &= \bigcap_{k=1}^{\infty} C_k \times C_k && \text{(By definition)} \\ &= \left(\bigcap_{k=1}^{\infty} C_k\right) \times \left(\bigcap_{k=1}^{\infty} C_k\right) && \text{(To be proved)} \\ &= C \times C && \text{(By definition.)} \end{aligned}$$

To prove that $\bigcap_{k=1}^{\infty} C_k \times C_k = \left(\bigcap_{k=1}^{\infty} C_k\right) \times \left(\bigcap_{k=1}^{\infty} C_k\right)$, start with the inclusion from left to right:

For all

$$(x, y) \in \bigcap_{k=1}^{\infty} C_k \times C_k$$

we have

$$(x, y) \in C_k \times C_k, \forall k \in \mathbb{N}.$$

By the definition of Cartesian product, we have

$$\begin{aligned} x &\in C_k, \forall k \in \mathbb{N}, \\ y &\in C_k, \forall k \in \mathbb{N}. \end{aligned}$$

Thus,

$$\begin{aligned} x &\in \bigcap_{k=1}^{\infty} C_k, \\ y &\in \bigcap_{k=1}^{\infty} C_k. \end{aligned}$$

Therefore,

$$(x, y) \in \left(\bigcap_{k=1}^{\infty} C_k\right) \times \left(\bigcap_{k=1}^{\infty} C_k\right), \forall (x, y) \in D,$$

which means

$$\bigcap_{k=1}^{\infty} C_k \times C_k \subseteq \left(\bigcap_{k=1}^{\infty} C_k \right) \times \left(\bigcap_{k=1}^{\infty} C_k \right).$$

Next, prove the inclusion from right to left. For all

$$(x, y) \in \left(\bigcap_{k=1}^{\infty} C_k \right) \times \left(\bigcap_{k=1}^{\infty} C_k \right)$$

we have

$$\begin{aligned} x &\in C_k, \forall k \in \mathbb{N}, \\ y &\in C_k, \forall k \in \mathbb{N}. \end{aligned}$$

By the definition of Cartesian product, this implies that

$$(x, y) \in C_k \times C_k, \forall k \in \mathbb{N}.$$

Since it satisfies the definition of intersection, we have $(x, y) \in \bigcap_{k=1}^{\infty} C_k \times C_k$, implying that

$$\left(\bigcap_{k=1}^{\infty} C_k \right) \times \left(\bigcap_{k=1}^{\infty} C_k \right) \subseteq \bigcap_{k=1}^{\infty} C_k \times C_k.$$

Therefore, we can conclude that the two sets are equal:

$$\bigcap_{k=1}^{\infty} C_k \times C_k = \left(\bigcap_{k=1}^{\infty} C_k \right) \times \left(\bigcap_{k=1}^{\infty} C_k \right).$$

(c) To prove that it is a perfect set, we need to show that every point in the set is a limit point of the set.

Theorem 1.7

- (i) The intersection of any number of closed sets is closed.
- (ii) The union of any number of open sets is open.

Since each D_k is closed, it follows from Theorem 1.7 that D is closed. Note that D_k consists of 4^k closed disjoint intervals, each of which

■

Problem 3. Zygmund p59 exercise 04

Construct a subset of $[0, 1]$ in the same manner as the Cantor set by removing from each remaining interval a subinterval of relative length $\theta, 0 < \theta < 1$. Show that the resulting set is perfect and has measure zero.

(a) To prove that the set C' is a perfect set, we need to show that it is closed and every point in the set is a limit point of the set.

Since each C'_k is closed, it follows from Theorem 1.7 that C' is closed.

Then show that every point in C' is a limit point of the set:

Case 1. Let $x \in C'$ be an endpoint of $I_k \subseteq C'_k$. Consider the intervals $I_k^i \subseteq C'_{k+i}$ with endpoint x , let x_1 be the other endpoint of $I_k^1 \subseteq C'_{k+1}$, x_2 be the other endpoint of $I_k^2 \subseteq C'_{k+2}$, ..., x_n be the other endpoint of $I_k^n \subseteq C'_{k+n}$.

We have

$$x_n \rightarrow x,$$

$$x_n \neq x,$$

$$x_n \in C'.$$

Thus, x is a limit point of C' .

Case 2. Suppose $x \in C'$ is not an endpoint of any interval consisting C' . $\forall n \in \mathbb{N}$, we have $x \in (a_n, b_n)$, where $a_n \in C'$ and $|a_n - x| < (\frac{1-\theta}{2})^n$. Let $x_n = a_n$, $\{x_n\}$ is the sequence s.t.

$$x_n \rightarrow x,$$

$$x_n \neq x,$$

$$x_n \in C'.$$

Thus, x is a limit point of C' .

We can conclude that every point in C' is a limit point of the set. Therefore, C' is perfect.
